(1) Machine learning is part of AI where computers learn from datas and improve automatically without coding again and again. it mainly works by finding patterns and giving output based on that.

Some points are:

- computer learn from data
- No need to program everything
- it find patterns in datas
- Used in many application
- Sometimes result is not always correct.

(3) Overfitting is when model learn too much from training data and remember everything including noise. Because of this is works very good on training data but not on new data.

Points:
- Model learn too much
- Remember all data
- includes noise also
- Not good for new data
- gives wrong result sometimes

(2) Supervised and unsupervised learning are types of machine learning. In supervised learning we give both input and output so model can learn from that and predict values.

Points:
- input and output both give
- Model learn from examples
- Used for prediction.

Unsupervised learning is when no output is given and model try to group the data by itself and find patterns.

Points:

- No output provided
- Model group data automatically
- Sometimes result is not very accurate.
- Used for clustering things.
